

# **The Magic Manual**

## **Section 10**

# **Heuristic**

**A guide for fabricators  
and users to stations from the  
Magic Mathworks Travelling Circus**

## 10. HEURISTIC

This word can be translated 'the art of discovery'. At these stations the investigators must fall back on first principles. They must discover for themselves the concepts involved. As throughout the Circus, the task is one of analysis, of dissecting the mathematical skeleton - the abstract structure - out of the physical corpse - the concrete embodiment. But, without a clue to the mathematics applicable, this is made one stage harder. Substations have therefore been introduced to offer help in this task:

10.1.1.2 serves 10.1.1.1.

10.1.3.2 serves 10.1.3.1.

10.1.6.1 serves 10.1.6.2, which in turn serves 10.1.6.3.

10.2.2 serves 10.2.1.

10.4.1 and 10.4.3 serve 10.4.2.

10.5.1 serves 10.5.2, which in turn serves 10.5.3.1 and 10.5.3.2.

10.1 This is a collection of games.

- c 10.1.1 - 10.1.5 are all games of subtraction in the general sense that successive moves narrow the options. So would 10.1.6.2 be if the players placed single cubes alternately. In the version given here, however, it is a competition rather than a game, designed as preparation for 10.1.6.3.

- p In the investigative spirit of the topic, once the winning strategy is found, the players can change the game itself.

### 10.1.1

#### 10.1.1.1 NIM

- c The winning strategy uses the binary system in the way expounded in:

#### 10.1.1.2 NIMROD

- p If smaller boards are tried, as suggested by the hardboard mask, the advantage shifts as follows:

<u>board</u>	<u>player favoured</u>	<u>winning move</u>
III III III	1st	2 matches from top row
II III III	1st	3 matches from bottom row
I II III	2nd	

Children are reluctant to reduce the board in this way. However, amongst others, these configurations occur as positions in the original game.

### 10.1.2 CHOMP

- c** The winning strategy is unknown in the general case. There is a proof that such exists for the first player. Sadly it is non-constructive.
- p** The special cases novices should study are a square board -  $4 \times 4$  is possible here - and an  $n \times 2$  board -  $6 \times 2$  is possible here: simple strategies exist for both.

### 10.1.3

#### 10.1.3.1 THE PIE GAME

- c** The structure is revealed by an isomorphic game:

#### 10.1.3.2 ALSO THE PIE GAME

In the first we have a model pie; in the second, a grid ruled in 3 directions. Corresponding to a number of slices in the former is a vector in the latter:

##### 10.1.3.1

"Take  $n$  red slices."  
"Take  $n$  blue slices."  
"Take  $n$  red and  $n$  blue slices."

##### 10.1.3.2

"Move  $n$  units west."  
"Move  $n$  units south."  
"Move  $n$  units west and  $n$  units south (i.e. southwest)."

With the given number of blue slices (8) and red slices (4), the first player can win by taking 1 blue slice.

- p** Exhibitors may choose to withhold 10.1.3.2 unless or until the time is ripe.

### 10.1.4 DOMINO BLOCK

- c** The second player can win by matching each move the first player makes with a point-symmetric one.
- p** Once the experimenters discover this strategy they can add interest by changing the number of players and the rules governing a move.

### **10.1.5 3-D Os & Xs**

- c** On the 3 x 3 x 3 board, used here, the first player can win in 4 moves by seizing the central site. Note that 4 sites are distinguished by the number of lines they command:
- centre (13), corner (7), centre-face (5), centre-edge (4).
- p** The game becomes interesting when the number of players is increased to 3 or 4 - which it can be quite simply by adding a new colour of marble.

### **10.1.6 TARTAN CHECKS**

- c** 4 colours must meet in each vertex. Consequently, a cube of a given colour is bordered by 8 dissimilar ones. The rule generates 2 basic colour patterns:

abab...

cdcd...,

where cubes of a given  
colour define a square grid,

abcdabcd...

cdabcdab...,

where cubes of a given  
colour define a rhombic grid.

- p** The activity is structured as follows:

#### **10.1.6.1 EDGES & CORNERS**

The experimenters establish 'the facts of the case' by obeying the rules.

#### **10.1.6.2 TARTAN BLOCK**

A simple game forces them to consider the disabling effect of cubes in combination. (The optimal strategy is to build a complete double row (as in 10.1.6.1) but then to displace the second row so that it forms the third - it is equally effective to adopt the same strategy with diagonals.)

#### **10.1.6.3 THE CHECKS CHALLENGE**

They apply what they have learnt.

A note on the title: the second word puns 'check' as a colour grid - of which a tartan is a special case, 'check' as a test that the stated rule has been followed and 'check' in the sense used in chess of 'putting a check on' your opponent's potential move(s).

## 10.2

### 10.2.1 SAFE QUEENS

- c** Beyond engendering an awareness of rows, columns and diagonals there would be little justification for this activity were it not for its inherent fascination.

Allowing rotations about the centre and reflections in symmetry axes, there are 2 solutions in the 5 x 5 case, 6 in the 7 x 7. Students should be urged to seek all these rather than press on to the 8 x 8 case. Unfortunately, the challenge of the full board is hard to resist.

- p** Up to 7 x 7 one can profitably adopt a strategy (modified as necessary) - displacing the pieces by series of knights' moves or similar. As it turns out, one can only deal with the 8 x 8 case by changing from a strategic approach to an exhaustive one, systematically working one's way across the board modifying an initial alignment of 8 queens in a row. Children rarely make the switch and resort to an ad hoc approach, which rarely leads to a solution: the problem is too complex combinatorially.

The bigger the board considered, the more carefully one must check for alignments.

### 10.2.2 SAFE QUEENS ON A 5 X 5 BOARD

- p** If translations are allowed, there are only 2 7 x 7 solutions and 1 5 x 5. This second station allows people to confirm that fact in the second case. But its real purpose is to encourage them to extend the approach to the first.

## 10.3

- p** 10.3.1 and 10.3.2 have been paired because in each case the answer to the question posed is 'No'.

The two stations serve to distinguish physical and logical possibility.

Without a proof - however rough-and-ready - one's answers to the questions will not convince.

### 10.3.1 GRANDPA'S ARMCHAIR

- p** It's difficult to get a feel for what's going on here without recording the results of trial moves. This provides a good opportunity for students to devise their own ikons or symbols.

One can prove the (negative) result by considering, for example, what happens to the sum of the Cartesian coordinates of a chair corner when it executes a  $1/4$ -turn.

The ancillary apparatus is intended for such investigations.

### **10.3.2 DOMINO TILINGS**

- p** The caption prepares the investigators for failure - however reluctant they might be to accept it.

A further exercise distinguishes *necessary* and *sufficient* conditions.

## **10.4 WEAVES**

- p** These are the functions of the ancillary pieces:

### **10.4.1 THE SPECIMEN WEAVE**

... presents the general case.

### **10.4.2 THE CHUNKY WEAVE HOLE**

... frames the question which it is the object of investigation **10.4** to answer: 'When is a check a possible weave?'

The dimensions of the hole are significant: it turns out that the condition necessary and sufficient for a check to be a possible weave is that in every  $2 \times 3$  rectangle at least one colour must repeat in a row or column.

### **10.4.3 THE SEE-THROUGH WEAVE BOARD**

... renders front and back of **THE CHUNKY WEAVE HOLE** visible simultaneously.

## **10.5**

- p** This investigation has 3 stages and children can stop at any one:

### **10.5.1 LATIN SQUARES**

The experimenters construct an order 3 Latin square, using coloured cups or coloured saucers.

### **10.5.2 GRAECO-LATIN SQUARES 1**

They make an orthogonal pair of the same order, pairing the cups and saucers.

### **10.5.3 GRAECO-LATIN SQUARES 2**

They attempt one of order 4:

#### **10.5.3.1**

... either by stacking pairs of coloured, interlocking cubes to make their cup-&-saucer pairs

#### **10.5.3.2**

... or by using the two attributes of playing cards: suit and value.

Most people find the second easier because the two component Latin squares are distinguished.

### **10.6 A DOMINO RECTANGLE**

- p** A standard set of dominoes is packed in an 8 x 7 grid, the spot number for each cell recorded and the dominoes removed. The exercise is to replace the dominoes.

The activity is more or less interesting and challenging according to how the dominoes are arranged. The cunning arrangement here is due to David Fielker.

The station might have been included in **10.3** in that it is as much to do with where dominoes *can't* go as where they *can*.

# DOMINO TILINGS

## First investigations

- ▶ A polyomino has any number of squares joined edge-to-edge:

- ▶ A domino is a polyomino of 2 squares:

- ▶ So a polyomino can only be covered exactly with dominoes ('tiled') if it has an even number of squares.
- ▶ On a checkerboard a domino must cover exactly 1 black square and 1 white square:

- ▶ So a checkered polyomino can only be tiled with dominoes if it has equal numbers of black and white squares.
- ▶ The face has 20 squares, an even number, but 9 are white and 11 are black.

- Can it be tiled with dominoes?

	NUMBER	TITLE
GROUP	10	HEURISTIC
STATION	10.3.2	DOMINO TILINGS
TOPIC	Necessary v. sufficient conditions	

### **What we have proved so far**

**'A polyomino which tiles with dominoes must have:**

- (1) an even number of squares,**
- (2) equal numbers of black and white squares.'**

**We don't need rule (1) as well as rule (2) because, if the numbers of black and white squares are equal, their total must be even. So all we need write is the black-&-white theorem:**

**'A polyomino which tiles with dominoes must have equal numbers of black and white squares.'**

### **The next challenge**

**The black-&-white condition is *necessary*.  
Is it also *sufficient*?**

**If it is, the *converse* of the black-&-white theorem is true:**

**'If a polyomino has equal numbers of black and white squares, it can be tiled with dominoes.'**

**If it is not, the converse is false.**

**This means you can draw a polyomino which has equal numbers of black and white squares but which does *not* tile with dominoes.**

● **Try!**

**Draw polyominoes on the squared board which contain equal numbers of black and white squares.**

**Try to tile them with the dominoes.**

PICTURE KEY	DESCRIPTION	TRADE NAME	U.K. SOURCE
a	<p>'face'</p> <p>The design should distinguish clearly the squares which are to be tiled - those in black or white - and those which are not - the 'eyes' and 'mouth'.</p> <p>Here, the piece of checkerboard shown - squares: 35 mm - is set in a matrix of blue expanded polyethylene, 'mouth' and 'eyes' indicated as shown,</p> <p>and the whole sandwiched between A4 Glodex sheets.</p>		local
b	<p>checkerboard, 35 mm squares, 8 x 8,</p> <p>300 mm square overall,</p> <p>faced with Glodex</p>		local
c	<p>dominoes, 35 mm x 70 mm, here in red perspex but 3 mm PVC easier to obtain</p> <p>Perspex has the pedagogic advantage that one can see that a domino covers exactly one black square and one white one.</p>	Amari Foam	Amari Plastics (address above)
